RESEARCH MEMORANDUM

SUMMARY OF TURBULENCE DATA OBTAINED DURING UNITED AIR

LINES FLIGHT EVALUATION OF AN EXPERIMENTAL

C BAND (5.5 CM) AIRBORNE WEATHER RADAR

By E. C. Coe and M. W. Fetner

SUMMARY

Data on atmospheric turbulence in the vicinity of thunderstorms obtained during a flight evaluation of an experimental C band (5.5 cm) airborne radar are summarized. The turbulence data were obtained with an NACA VGH recorder installed in a United Air Lines DC-3 airplane.

INTRODUCTION

Several studies have been made in recent years on the use of airborne radar as a navigational aid for the pilot (see, for example, refs. 1 and 2). As a continuation of this work, United Air Lines, Inc., has recently completed a flight evaluation of an experimental C band (5.5 cm) airborne weather radar to determine its application in avoiding regions of severe turbulence in thunderstorm areas. Results from some phases of the work have been presented in reference 3. The NACA assisted in this work by providing an NACA VGH recorder (ref. 4) for obtaining information on the turbulence encountered on the flights and by evaluating the records for correlation with the radar indications. This report was prepared to summarize the gust-velocity data obtained from the VGH records.

SCOPE OF TESTS AND APPARATUS

A total of 40 flights was made by United Air Lines, Inc., with a Douglas DC-3 airplane between June and October 1953 in the vicinity of Denver, Colo. Of these flights, 12 were made for the technical evaluation and adjustment of the radar, and the remaining 28 flights were made in surveying thunderstorm areas to obtain radar and turbulence data. A total of approximately 80 hours of flight was made in the immediate vicinity of thunderstorms.

The NACA VGH recorder installed in the airplane to obtain gust data provides a continuous record of airspeed, pressure altitude, and normal acceleration. A detailed description of the instrument is given in reference 4. For use in the present tests, the pitot and static leads from the instrument were connected to the airplane service system and the accelerometer transmitter was mounted near the center of gravity of the airplane. The airspeed system was calibrated in flight by United Air Lines, Inc. In addition to 1-minute timing marks, a separate reference mark was impressed on the VGH record each time a photograph was taken of the radar scope in order to synchronize the turbulence and radar data.

EVALUATION AND PRESENTATION OF DATA

The evaluation of the VGH records consisted of reading the individual acceleration peaks and the associated airspeed and altitude to determine the derived gust velocities U_{de} above a threshold of 10 fps. The derived gust velocities are defined by equation (11) of reference 5. These velocities are about 50 to 70 percent larger than the velocities computed according to the gust-velocity scale used in past radar evaluations (ref. 1).

The values of the positive and negative gust velocities above a threshold of 10 fps derived from the VGH records are summarized by date and flight number in table I. The radar picture numbers in this table correspond to the United Air Lines numbering of their photographs of the radar scope. The photographs were taken at nonuniform time intervals and, in many cases, a number of gusts were encountered in the intervals between successive photographs. To assist in correlating the photographs with the gust data, each gust evaluated from the records has been identified in the table according to the 1/2-minute time interval that the gust was encountered after the time the photograph was taken. For additional information, the pressure altitude, airspeed, and acceleration read from the record are also noted in the table for each gust evaluated.

COMMENT

The values of gust velocity summarized in table I are in agreement with other gust measurements taken by the NACA for similar flights near or below thunderstorms. Since the present flights did not, in general,

penetrate the thunderstorms, the gust velocities are lower than might be expected within the more active portions of thunderstorms.
